

Why smooth the 'halo' tracer? -- seed 1, $z=10.307$ (y-index=150 of 300). Unsmoothed panel uses its OWN colour scale ($1.82\text{e-}16$ vs native's $9.96\text{e-}17$ Mpc/s, $2\times$ larger) -- the sparse tracer (21523/27000000 cells occupied, 24115 objects) has near-empty real-space structure, so its raw overdensity is shot-noise-dominated and the $1/k^2$ reconstruction kernel amplifies that into unphysical outliers; $R_s=18.4$ Mpc suppresses the small scales those outliers live on.
